Building a mixture model

General formulation: Data are drawn from a *convex combination of components*

For K groups/clusters:

$$\begin{aligned} p(y) &= \eta_1 p(y|\boldsymbol{\theta}_1) + \dots + \eta_K p(y|\boldsymbol{\theta}_K) \\ &= \sum_{k=1}^K \eta_k p(y|\boldsymbol{\theta}_k) \end{aligned}$$

- $\boldsymbol{\eta} = (\eta_1, \dots, \eta_K)$: Mixture weights; $\sum_{k=1}^K \eta_k = 1$
- $p(y|\boldsymbol{\theta}_k)$: k^{th} Mixture component; same parametric family

Building a mixture model

Figure here to show flexibility of motivating example - three panels, vary means and/or sds

Mixture model ingredients

Discuss how the basic formulation is flexible and can present different model types Examples

- Latent class analysis
- Latent class regression
- Hidden Markov models

Focus of this tutorial: cross-sectional data

- Finite mixture
- Dirichlet Process mixture (to infinity and beyond)
- Profile regression (joint clustering in x and y)

Bayesian approaches

- 1 Why mixture models/motivation
- 2 Finite mixture models
- 3 Dirichlet Process Mixture models
- 4 Profile regression
- 5 Model fitting and inference
- 6 References

Setup

Assume a fixed number of components K

Each data point has a probability of belonging to each

Estimating a Finite Mixture Model

Aim is to learn $\eta_{1,\dots,K}$ and $\theta_{1,\dots,K}$

Both are conditional on k

Introduce a latent variable, z

- One per observation: y_i, z_i
- Each z_i is discrete: $1, \dots, K$ with $Pr(z_i = k) = \eta_k$ [check thesis]
- y_i belongs to cluster k iff $z_i = k$

Estimating a Finite Mixture Model

$$Pr(z_i = k | y_i, \cdot) = \frac{p(y_i | \theta_k, z_i = k) Pr(z_i = k)}{\sum_{l=1}^K p(y_i | \theta_l, z_i = l) Pr(z_i = l)}$$
